## Inductive Definitions

Carlo Angiuli

B522: PL Foundations  
January 15, 2025

Our first order of business will be to define the set of (valid) expressions of a language, introducing us to the notion of an *inductive definition* by a collection of *inference rules*. This lecture will introduce inference rules, what they mean, how to reason about them, and a few applications. The material may seem technical at first, but we will see many more examples of these concepts in the coming lectures.

Abstract syntax and inductive definitions are covered in Chapters 1 and 2 of Harper [Har16], but with a different presentation.

### 1 BNF grammars

The most concise way to define a set of expressions, and one you may have seen before, is to write a formal grammar in *Backus–Naur form* (BNF). In C311/B521 you might have written down the syntax of a simple “programming language” of booleans as follows:

$$\text{Expressions } e ::= \text{ true } \mid \text{ false } \mid (\text{not } e) \mid (\text{if } e \ e \ e)$$

In this class we are not using Racket, so we will instead write:

$$\text{Expressions } e ::= \text{ true } \mid \text{ false } \mid \text{not}(e) \mid \text{if}(e, e, e)$$

*Remark 2.1.* In practice, one often wants a friendlier notation for if-expressions, such as `if  $e$  then  $e$  else  $e$` . For now we are talking about a mathematical or *abstract* conception of the syntax of a programming language, divorced from questions such as how to type it into a computer. Soon enough we will allow ourselves to write friendlier *concrete* syntax for our own sake, with the understanding that it is (in this class) a shorthand for abstract syntax.

Here  $e$  ranges over the set of all possible expressions, which are true, false,  $\text{not}(e)$  where  $e$  is an expression, and  $\text{if}(e, e, e)$  where each of these  $e$ s is a (possibly different) expression. (Sometimes people write  $\text{if}(e, e', e'')$  to make it clearer that these  $e$ s are not required to be the same.)

*Remark 2.2.* More precisely, we are defining a single grammatical category of *expressions*, corresponding to the *nonterminal*  $e$  on the left; there are two *terminal* symbols, namely true and false, and the vertical bars indicate alternatives.

*Exercise 2.3.* Are the following valid expressions?

- true — yes
- $\text{not}(\text{true})$  — yes
- $\emptyset$  — no
- $\text{if}(\text{true}, \text{false})$  — no
- $\text{not}$  — no(!)
- $\text{if}(\text{true}, \text{false}, \emptyset)$  — no

Note that the clauses of the grammar not only indicate what *is* a valid term but also what *isn't*: everything else.

**Definition 2.4.**  $e$  is a valid expression if and only if:

- $e = \text{true}$  or
- $e = \text{false}$  or
- $e = \text{not}(e')$  where  $e'$  is a valid expression or
- $e = \text{if}(e_1, e_2, e_3)$  where  $e_1, e_2, e_3$  are valid expressions.

The “only if” here will be crucial to our ability to reason about the properties of valid expressions.

*Remark 2.5.* The HtDP-heads among you may imagine something like the following data definition:

```
; An Exp is one of:  
; - true  
; - false  
; - (make-not Exp)  
; - (make-if Exp Exp Exp)
```

## 2 Inference rules

To formally explain why  $\text{if}(\text{not}(\text{true}), \text{false}, \text{true})$  is a valid expression, we might argue as follows:

- $\text{if}(\text{not}(\text{true}), \text{false}, \text{true})$  is an expression because
  - $\text{not}(\text{true})$  is an expression because
    - $\text{true}$  is an expression
  - $\text{false}$  is an expression
  - $\text{true}$  is an expression

The outermost step of the argument is an instance of the general fact that  $\text{if}(e_1, e_2, e_3)$  is an expression if  $e_1$  is an expression,  $e_2$  is an expression, and  $e_3$  is an expression; in this case  $e$  is  $\text{not}(\text{true})$  and so seeing that it is an expression relies in turn on the general fact that  $\text{not}(e)$  is an expression if  $e$  is an expression, and that  $\text{true}$  is an expression.

Let us introduce some terminology and notation to simplify this argument. We will write

$$e \text{ exp}$$

for the assertion that  $e$  is an expression. We call  $\text{exp}$  a *judgment*, in the sense that this assertion “judges” that  $e$  is indeed an expression. (We can also call it an *assertion* or a *predicate*.)

There are four ways to judge  $e$  to be an expression. One is that  $\text{not}(e)$  is an expression if  $e$  is an expression. We write this as an *inference rule* with one premise ( $e \text{ exp}$ ) and one conclusion ( $\text{not}(e) \text{ exp}$ ).

$$\frac{e \text{ exp}}{\text{not}(e) \text{ exp}}$$

Two of the remaining three inference rules have no premises, while the final one has three premises.

$$\frac{}{\text{true exp}} \quad \frac{}{\text{false exp}} \quad \frac{e_1 \text{ exp} \quad e_2 \text{ exp} \quad e_3 \text{ exp}}{\text{if}(e_1, e_2, e_3) \text{ exp}}$$

*Remark 2.6.* An inference rule with zero premises is called an *axiom*.

One benefit of inference rule notation is that we can chain these rules together:

$$\frac{\frac{\frac{}{\text{true exp}}{\text{not(true) exp}} \quad \frac{}{\text{false exp}} \quad \frac{}{\text{true exp}}}{\text{if(not(true), false, true) exp}}}{}$$

*Remark 2.7.* Chaining together inference rules as above forms a *derivation tree* whose root (at the bottom) can be concluded from its leaves/premises (at the top). If every leaf is an axiom then there are no remaining premises, the conclusion holds unconditionally, and we say that the derivation is *closed*.

Schematic picture of a derivation with wedges indicating subderivations.

*Exercise 2.8.* Write a (closed) derivation of  $\text{not}(\text{not}(\text{true})) \text{ exp}$ .

*Remark 2.9.* Note that we can instantiate  $e', e_1, e_2, e_3$  in the rules for  $\text{not}$  and  $\text{if}$  with any valid expression. In that way, those rules really stand for an infinite family of rules of the form “if  $[blank]$  is an expression then  $\text{not}([blank])$  is an expression,” whereas the rules for  $\text{true}$  and  $\text{false}$  really are just singular rules.

Once again, crucially, we take the four inference rules above as specifying not only when something *can* be judged to be an expression but also when something *cannot*.

**Definition 2.10.** The judgment  $e \text{ exp}$  holds if and only there is a closed derivation tree with conclusion  $e \text{ exp}$ , built only out of the rules:

$$\frac{}{\text{true exp}} \quad \frac{}{\text{false exp}} \quad \frac{e \text{ exp}}{\text{not}(e) \text{ exp}} \quad \frac{e_1 \text{ exp} \quad e_2 \text{ exp} \quad e_3 \text{ exp}}{\text{if}(e_1, e_2, e_3) \text{ exp}}$$

This is essentially just a rephrasing of Definition 2.4.

*Remark 2.11.* We can read inference rules from top to bottom: “if  $e \text{ exp}$  then  $\text{not}(e) \text{ exp}$ .” But we can also read them from bottom to top: “to show that  $\text{not}(e) \text{ exp}$ , we can show that  $e \text{ exp}$ .” But importantly, inference rules are more than just random implications: they are always the *defining clauses of a judgment*.

## 2.1 Aside: abstract syntax trees

If we turn the derivation of  $\text{if}(\text{not}(\text{true}), \text{false}, \text{true}) \text{ exp}$  upside-down, we can see it as an *abstract syntax tree*, where each node corresponds to the rule being invoked (equivalently, the topmost constructor of the expression), and its child trees correspond to the list of immediate subexpressions.

**Definition 2.12.**  $e$  is a valid abstract syntax tree if and only if:

•  $e = \boxed{\text{true}}$  or

•  $e = \boxed{\text{false}}$  or

•  $e = \begin{array}{c} \boxed{\text{not}} \\ | \\ e' \end{array}$  where  $e'$  is a valid abstract syntax tree or

•  $e = \begin{array}{c} \boxed{\text{if}} \\ / \quad | \quad \backslash \\ e_1 \quad e_2 \quad e_3 \end{array}$  where  $e_1, e_2, e_3$  are valid abstract syntax trees.

Again, this is essentially just a rephrasing of Definitions 2.4 and 2.10.

*Remark 2.13.* These trees show up in actual implementations of programming languages, sometimes called *abstract syntax trees* or *parse trees*, as the data structures generated by parsers.

## 2.2 More inductive structures

Inference rules are a powerful tool that will allow us to define a great many “inductive” structures, structures that are defined by a collection of (potentially self-referential) clauses and no others.

*Example 2.14.* We define the natural numbers  $\mathbb{N}$  as follows:

$$\text{Natural numbers } n ::= \text{zero} \mid \text{suc}(n)$$

where the “successor” of  $n$  represents  $n + 1$ . Equivalently, the judgment  $n \text{ nat}$  is defined by the collection of inference rules:

$$\frac{}{\text{zero nat}} \qquad \frac{n \text{ nat}}{\text{suc}(n) \text{ nat}}$$

*Example 2.15.* We could add natural numbers to our programming language:

$$\begin{array}{l} \text{Expressions } e ::= \text{ true } \mid \text{ false } \mid \text{ not}(e) \mid \text{ if}(e, e, e) \\ \quad \quad \quad \mid \text{ zero } \mid \text{ suc}(e) \mid \text{ zero?}(e) \end{array}$$

Equivalently,

$$\begin{array}{c} \frac{}{\text{true exp}} \quad \frac{}{\text{false exp}} \quad \frac{e \text{ exp}}{\text{not}(e) \text{ exp}} \quad \frac{e_1 \text{ exp} \quad e_2 \text{ exp} \quad e_3 \text{ exp}}{\text{if}(e_1, e_2, e_3) \text{ exp}} \\ \frac{}{\text{zero exp}} \quad \frac{e \text{ exp}}{\text{suc}(e) \text{ exp}} \quad \frac{e \text{ exp}}{\text{zero?}(e) \text{ exp}} \end{array}$$

We can also define multiple grammatical categories / judgments simultaneously with reference to one another.

*Example 2.16.* We define lists of natural numbers as follows:

$$\begin{array}{l} \text{Natural numbers } n ::= \text{ zero } \mid \text{ suc}(n) \\ \text{Lists of naturals } \ell ::= \text{ empty } \mid \text{ cons}(n, \ell) \end{array}$$

Equivalently,

$$\frac{}{\text{zero nat}} \quad \frac{n \text{ nat}}{\text{suc}(n) \text{ nat}} \quad \frac{}{\text{empty natlist}} \quad \frac{n \text{ nat} \quad \ell \text{ natlist}}{\text{cons}(n, \ell) \text{ natlist}}$$

*Example 2.17.* We define even and odd natural numbers as follows:

$$\begin{array}{l} \text{Evens } e ::= \text{ zero } \mid \text{ suc}(o) \\ \text{Odds } o ::= \text{ suc}(e) \end{array}$$

Equivalently,

$$\frac{}{\text{zero even}} \quad \frac{o \text{ odd}}{\text{suc}(o) \text{ even}} \quad \frac{e \text{ even}}{\text{suc}(o) \text{ odd}}$$

*Remark 2.18.* BNF grammars will not be able to fully capture most of the languages we consider throughout the semester, because they have an infinite number of grammatical categories (types) and/or binding (variables); for these features we will need to use inference rules. However, BNF grammars will remain a convenient way to summarize some systems of inference rules.

So far all of our judgments have been *unary*: assertions about a single expression (often, that it is well-formed). We can also define *binary* judgments that make a joint assertion about two things.

*Example 2.19.* The binary judgment

$$n \text{ doubledls } n'$$

is defined by the following inference rules:

$$\frac{}{\text{zero doubledls zero}} \qquad \frac{n \text{ doubledls } n'}{\text{suc}(n) \text{ doubledls } \text{suc}(n')}$$

*Exercise 2.20.* There is exactly one concrete  $n$  for which we can derive

$$\text{suc}(\text{zero}) \text{ doubledls } n$$

What is that  $n$ ? Write the derivation of the above judgment.

### 2.3 Reasoning about inductive structures

**Lemma 2.21.** *If  $n$  even then  $\text{suc}(\text{suc}(n))$  even.*

*Proof.* Suppose we have a derivation of  $n$  even. Then we can add two more rules to the bottom of that derivation to form a derivation of  $\text{suc}(\text{suc}(n))$  even as required:

$$\frac{\frac{\frac{\vdots}{n \text{ even}}{\text{suc}(n) \text{ odd}}}{\text{suc}(\text{suc}(n)) \text{ even}}}{\square}$$

So far we have used the “if” direction of a number of inductive definitions (as in Definitions 2.4, 2.10 and 2.12) to show that certain judgments hold, and we have used the “only if” direction to show that certain judgments do *not* hold (e.g.,  $\emptyset$  is not an expression). We can also use the “only if” direction to prove positive properties of judgments.

**Lemma 2.22** (Inversion for suc). *If  $\text{suc}(m)$  nat then  $m$  nat.*

*Proof.* The judgment  $n$  nat holds *only if* there is a derivation of  $n$  nat built out of repeated applications of the two rules

$$\frac{}{\text{zero nat}} \qquad \frac{n \text{ nat}}{\text{suc}(n) \text{ nat}}$$

In particular, any derivation of  $\text{suc}(m)$  nat must end with an application of one of these two rules. It cannot end with an application of the first rule, because then it would be a derivation of zero nat. So it must end with the second rule applied to a complete derivation of its premise  $m$  nat. From this we conclude  $m$  nat.  $\square$

*Remark 2.23.* The above argument is an instance of a common reasoning pattern called *rule induction*, which we will make more precise shortly.

*Remark 2.24.* Whereas the second rule says that  $m \text{ nat}$  is a *sufficient* condition for concluding that  $\text{succ}(m) \text{ nat}$ , Lemma 2.22 states that it is in fact a *necessary* condition: that rule is the *only* way to conclude that  $\text{succ}(m) \text{ nat}$ . In other words, we can “run the rule backwards,” which is why it’s called an *inversion lemma*.

### 3 Least sets

Before giving any more examples of rule induction, I want to pause and derive it mathematically from the “if and only if” characterization of inductive structures.

Let us write  $\text{Exp}$  for the set of valid expressions: the set of  $e$  for which  $e \text{ exp}$  holds. Recall that by Definition 2.10,  $e \in \text{Exp}$  if and only if we have a derivation tree with conclusion  $e \text{ exp}$  built only out of the following rules:

$$\frac{}{\text{true exp}} \quad \frac{}{\text{false exp}} \quad \frac{e \text{ exp}}{\text{not}(e) \text{ exp}} \quad \frac{e_1 \text{ exp} \quad e_2 \text{ exp} \quad e_3 \text{ exp}}{\text{if}(e_1, e_2, e_3) \text{ exp}}$$

Let us refer to these four rules as  $E$ .

**Definition 2.25.** A set  $X$  is *E-closed* if the following four properties hold:

- $\text{true} \in X$ ,
- $\text{false} \in X$ ,
- $\text{not}(x) \in X$  whenever  $x \in X$ , and
- $\text{if}(x_1, x_2, x_3) \in X$  whenever  $x_1, x_2, x_3 \in X$ .

**Theorem 2.26.** *The set of expressions  $\text{Exp}$  is the least E-closed set; that is, (1)  $\text{Exp}$  is E-closed, and (2) for any E-closed set  $X$ , we have  $\text{Exp} \subseteq X$ .*

*Proof.*

1. First we prove that  $\text{Exp}$  is  $E$ -closed. There are derivations of  $\text{true exp}$  and  $\text{false exp}$ , so by definition we have  $\text{true}, \text{false} \in \text{Exp}$ . Using the  $\text{not}$  rule, whenever we have a derivation of  $e \text{ exp}$  we can build a derivation of  $\text{not}(e) \text{ exp}$ . Finally, using the  $\text{if}$  rule, whenever we have derivations of  $e_1 \text{ exp}$  and  $e_2 \text{ exp}$  and  $e_3 \text{ exp}$  we can build a derivation of  $\text{if}(e_1, e_2, e_3)$ .

2. Suppose that  $X$  is  $E$ -closed and that we have a derivation of  $e$  exp; we translate that derivation into a proof that  $e \in X$ . Our derivation of  $e$  exp must end with one of the four rules of  $E$ . If it ends in true exp, then we must prove  $\text{true} \in X$ , which is true by  $E$ -closure. (Similarly for false exp.) Alternatively, it could end with the following rule:

$$\frac{\frac{\vdots}{e \text{ exp}}}{\text{not}(e) \text{ exp}}$$

In that case, we have at hand a derivation tree of  $e$  exp which is shorter than the tree we started with, and we can recursively translate that derivation into a proof that  $e \in X$ . Once that process is completed, we can apply  $E$ -closure to conclude that  $\text{not}(e) \in X$  as well. (The case for if is similar.)  $\square$

*Example 2.27.* For a concrete example of the above proof, suppose that  $X$  is  $E$ -closed and show that  $\text{if}(\text{not}(\text{true}), \text{false}, \text{true}) \in X$  by converting each inference rule in the derivation below to an application of  $E$ -closure:

$$\frac{\frac{\text{true exp}}{\text{not}(\text{true}) \text{ exp}} \quad \text{false exp} \quad \text{true exp}}{\text{if}(\text{not}(\text{true}), \text{false}, \text{true}) \text{ exp}}$$

*Remark 2.28.* The  $E$ -closure of  $\text{Exp}$  corresponds to the “if” direction of our definition: if we can build a derivation out of the rules of  $E$ , then we have a valid expression. The leastness corresponds to the “only if” direction:  $\text{Exp}$  contains only things built out of the rules of  $E$ . If  $\text{Exp}$  contained additional expression(s) *not* built out of the rules, those expressions would not be in every  $E$ -closed set.

Let’s look at a more familiar example next.

**Definition 2.29.** A set  $X$  is  $N$ -closed if  $0 \in X$  and  $n \in X \implies n + 1 \in X$ .

**Theorem 2.30.** The natural numbers  $\mathbb{N}$  are the least  $N$ -closed set.

Examples of other  $N$ -closed sets include  $\mathbb{Z}$ ,  $\mathbb{R}$ ,  $\mathbb{N} \cup \{-1\}$ , ... all of which satisfy the necessary closure conditions but include superfluous elements.

The characterization of  $\mathbb{N}$  as the least  $N$ -closed set implies the principle of mathematical induction.

**Theorem 2.31** (Mathematical induction). *To prove that  $P(n)$  holds for all  $n \in \mathbb{N}$ , it suffices to show that  $P(0)$  and  $\forall n \in \mathbb{N}.P(n) \implies P(n+1)$ .*

*Proof.* Define  $\Sigma_P = \{n \in \mathbb{N} \mid P(n)\}$ . Clearly  $\Sigma_P \subseteq \mathbb{N}$  by construction. The hypotheses imply that  $\Sigma_P$  is  $N$ -closed, so by Theorem 2.30 we have  $\mathbb{N} \subseteq \Sigma_P$ . Hence  $\mathbb{N} = \Sigma_P$  and thus  $P(n)$  for all  $n$ .  $\square$

Similarly, our characterization of  $\text{Exp}$  as the least  $E$ -closed set implies a principle of *rule induction*: to prove a property  $P$  for all expressions, we must show that the subset of expressions satisfying  $P$  is  $E$ -closed. That is, the property  $P$  is preserved by every inference rule.

**Theorem 2.32** (Rule induction for  $\text{Exp}$ ). *To prove that a property  $P(e)$  holds for all  $e \in \text{Exp}$ , it suffices to show that:*

- $P(\text{true})$ ,
- $P(\text{false})$ ,
- for every  $e$ , if  $P(e)$  then  $P(\text{not}(e))$ , and
- for every  $e_1, e_2, e_3$ , if  $P(e_1)$ ,  $P(e_2)$ , and  $P(e_3)$ , then  $P(\text{if}(e_1, e_2, e_3))$ .

*Proof.* Define  $\Sigma_P = \{e \in \text{Exp} \mid P(e)\}$ . Clearly  $\Sigma_P \subseteq \text{Exp}$  by construction. The hypotheses imply that  $\Sigma_P$  is  $E$ -closed, so by Theorem 2.26 we have  $\text{Exp} \subseteq \Sigma_P$ . Hence  $\text{Exp} = \Sigma_P$  and thus  $P(e)$  for all  $e \in \text{Exp}$ .  $\square$

## 4 Rule induction

**Theorem 2.33** (Rule induction for  $\text{nat}$ ). *To prove that a property  $P(n)$  holds for all  $n \in \text{nat}$ , it suffices to show that:*

- $P(\text{zero})$  and
- for every  $n$ , if  $P(n)$  then  $P(\text{suc}(n))$ .

**Lemma 2.34.** *If  $n \in \text{nat}$  then there exists some  $n'$  such that  $n \text{ doubledls } n'$ .*

*Proof.* We prove  $P(n) = \text{“there exists some } n' \text{ such that } n \text{ doubledls } n'\text{”}$  by rule induction. We must show that  $P$  is closed under the rules for the  $\text{nat}$  judgment, of which there are two.

- The first rule is:

$$\frac{}{\text{zero nat}}$$

We must show that  $P$  holds in this case, i.e. that  $P(\text{zero})$  holds, i.e. that there exists some  $n'$  such that  $\text{zero doubledls } n'$ . We choose  $n' = \text{zero}$ , because:

$$\frac{}{\text{zero doubledls zero}}$$

- The second rule is:

$$\frac{n \text{ nat}}{\text{suc}(n) \text{ nat}}$$

We must show that if the premise satisfies  $P$  (this is called our *inductive hypothesis*), then the conclusion satisfies  $P$ . That is, we must show that for all  $n$ , if  $P(n)$  holds then  $P(\text{suc}(n))$  holds. Unfolding the definition of  $P$ , our inductive hypothesis  $P(n)$  is that there exists  $n'$  such that  $n \text{ doubledls } n'$ . We must show that  $P(\text{suc}(n))$  holds, which is to say that there exists  $n''$  such that  $\text{suc}(n) \text{ doubledls } n''$ . We choose  $n'' = \text{suc}(\text{suc}(n'))$  because:

$$\frac{n \text{ doubledls } n'}{\text{suc}(n) \text{ doubledls } \text{suc}(\text{suc}(n'))} \quad \square$$

Inversion Lemma 2.22 also follows from rule induction, for the property  $P(n) = \text{“}n \text{ nat, and if } n \text{ is of the form } \text{suc}(n') \text{ for some } n', \text{ then } n' \text{ nat.} \text{”}$

**Theorem 2.35** (Rule induction for doubledls). *To prove that a property  $P(n, n')$  holds for all  $n \text{ doubledls } n'$ , it suffices to show that:*

- $P(\text{zero}, \text{zero})$  and
- for all  $n, n'$ , if  $P(n, n')$  then  $P(\text{suc}(n), \text{suc}(\text{suc}(n')))$ .

**Lemma 2.36.** *If  $n \text{ doubledls } n'$  then  $n'$  even.*

*Proof.* We prove  $P(n, n') = \text{“}n' \text{ even} \text{”}$  by rule induction. There are two cases:

- Case 1:

$$\frac{}{\text{zero doubledls zero}}$$

We must prove that the conclusion satisfies  $P$ , i.e.  $P(\text{zero}, \text{zero})$ , or that zero even. This is an axiom.

- Case 2:

$$\frac{n \text{ doubledls } n'}{\text{suc}(n) \text{ doubledls } \text{suc}(\text{suc}(n'))}$$

We must prove that  $P$  is closed under this rule: in other words, if  $P(n, n')$  holds then  $P(\text{suc}(n), \text{suc}(\text{suc}(n')))$  holds. Our inductive hypothesis  $P(n, n')$  is that  $n'$  even, and we must prove that  $\text{suc}(\text{suc}(n'))$  even. We already proved this in Lemma 2.21.  $\square$

**Lemma 2.37.** *If  $n$  doubledls  $n'$  and  $n$  doubledls  $n''$  then  $n' = n''$ .*

*Proof.* We prove  $P(n, n') = \text{“for all } n'' \text{ for which } n \text{ doubledls } n'', \text{ we have } n' = n''\text{”}$  by rule induction (on  $n$  doubledls  $n'$ ). There are two ways that the derivation of  $n$  doubledls  $n'$  can end:

- Case 1:

$$\frac{}{\text{zero doubledls zero}}$$

Show that  $P(\text{zero}, \text{zero})$ : if zero doubledls  $n''$ , then zero =  $n''$ . This follows by inversion, because the only rule that could derive such a thing is

$$\frac{}{\text{zero doubledls zero}}$$

Therefore  $n'' = \text{zero}$ , which is what we wanted to show.

- Case 2:

$$\frac{n \text{ doubledls } n'}{\text{suc}(n) \text{ doubledls } \text{suc}(\text{suc}(n'))}$$

Prove  $P(n, n')$  implies  $P(\text{suc}(n), \text{suc}(\text{suc}(n')))$ . The latter property is: if  $\text{suc}(n)$  doubledls  $n''$ , then  $\text{suc}(\text{suc}(n')) = n''$ . Our inductive hypothesis is the analogous statement about the premise: if  $n$  doubledls  $m$  then  $n' = m$ .

By inversion on the supposed derivation of  $\text{suc}(n)$  doubledls  $n''$ , only one rule applies:

$$\frac{n \text{ doubledls } m'}{\text{suc}(n) \text{ doubledls } \text{suc}(\text{suc}(m'))}$$

This tells us that  $n''$  is of the form  $\text{suc}(\text{suc}(m'))$ , so it remains to prove that  $\text{suc}(\text{suc}(m')) = \text{suc}(\text{suc}(n'))$ . By  $n$  doubledls  $n'$  and  $n$  doubledls  $m'$  and our inductive hypothesis,  $m' = n'$ .  $\square$

The above proof actually uses *nested* rule induction: we consider the two cases of  $n$  doubledIs  $n'$ , and in each case, we consider the two cases of  $n$  doubledIs  $n''$  (implicitly, in our appeal to inversion).

By Lemmas 2.34 and 2.37, for every  $n$  nat there is exactly one  $n'$  such that  $n$  doubledIs  $n'$ . In other words, doubling is in fact a *function* on natural numbers. We will often use inference rules to define functions in this way.

**Theorem 2.38** (Structural recursion for nat). *To define a function  $f$  on natural numbers, one must:*

- define  $f(\text{zero})$ , and
- define  $f(\text{suc}(n))$  for arbitrary  $n$ , given the value of  $f(n)$ .

*Proof.* As with doubledIs, we can define a binary judgment  $n$  maps-to  $n'$  by the inference rules:

$$\frac{}{\text{zero maps-to } \dots} \qquad \frac{n \text{ maps-to } n'}{\text{suc}(n) \text{ maps-to } (\dots n' \dots)}$$

The proofs of Lemmas 2.34 and 2.37 show that for any  $n$  nat there is exactly one  $n'$  for which  $n$  maps-to  $n'$ , so that maps-to is the graph of a function.  $\square$

To perform rule induction on mutually-defined judgments, we need mutual induction hypotheses.

**Theorem 2.39** (Rule induction for even/odd). *If*

- $P(\text{zero})$ ,
- for all  $o$  odd,  $Q(o) \implies P(\text{suc}(o))$ , and
- for all  $e$  even,  $P(e) \implies Q(\text{suc}(e))$ ,

*then  $P(e)$  holds for all  $e$  even and  $Q(o)$  holds for all  $o$  odd.*

**Theorem 2.40.** *If  $e$  even then  $e$  nat, and if  $o$  odd then  $o$  nat.*

*Proof.* We prove these by mutual rule induction.

- For the rule

$$\frac{}{\text{zero even}}$$

we must show zero nat, which is true by an axiom.

- For the rule

$$\frac{o \text{ odd}}{\text{suc}(o) \text{ even}}$$

our inductive hypothesis is  $o \text{ nat}$  and we must show  $\text{suc}(o) \text{ nat}$ , which holds by the  $\text{suc}$  rule for  $\text{nat}$ .

- For the rule

$$\frac{e \text{ even}}{\text{suc}(e) \text{ odd}}$$

our inductive hypothesis is  $e \text{ nat}$  and we must show  $\text{suc}(e) \text{ nat}$ , which holds by the  $\text{suc}$  rule for  $\text{nat}$ .  $\square$

*Remark 2.41.* HtDP-heads might have noticed

collection of inference rules : data definition :: rule induction : template

except that rule induction is about constructing a *proof* out of the input derivation. Structural recursion brings us full circle, using rule induction as a means of defining an ordinary function using a recursive template.

## 5 Evaluation

I didn't want to go a whole lecture without saying anything about programming languages. Going back to the boolean expression language from the beginning of the lecture, we can use inference rules to define a binary *evaluation* judgment,  $e \Downarrow e'$ , which explains how to recursively simplify any expression  $e$ .

$$\frac{}{\text{true} \Downarrow \text{true}} \quad \frac{}{\text{false} \Downarrow \text{false}} \quad \frac{e \Downarrow \text{true}}{\text{not}(e) \Downarrow \text{false}} \quad \frac{e \Downarrow \text{false}}{\text{not}(e) \Downarrow \text{true}}$$

$$\frac{e_1 \Downarrow \text{true} \quad e_2 \Downarrow e'_2}{\text{if}(e_1, e_2, e_3) \Downarrow e'_2} \quad \frac{e_1 \Downarrow \text{false} \quad e_3 \Downarrow e'_3}{\text{if}(e_1, e_2, e_3) \Downarrow e'_3}$$
